LogiMod 2022

The LogiMod is simply a "mode" that allows you to modify two input signals using 32 different algorithms. The main objective is to simply make two input signals that differ in intensity based on the input voltage. Main Features: 32

Modes: You can create a new mode by using "Mode # New"
High and Low - Choosing the High and Low the audio signal.
Left and Right - Choosing the Left and Right the audio signal.
Select - Using the "Select" knob you can select a mode from the list of 32. High and Low - Choosing the High and Low the input signal. Left and Right - Choosing the Left and Right the input signal. Select - Using the "Select" knob you can select a mode from the list of 32. Saw - Using the "Saw" you can make your audio signal vary in intensity with a sawtooth. Morphing - Using the "Morphing" you can make your audio signal change over time in intensity. Pulse - Using the "Pulse" you can make your audio signal vary in intensity with a square wave. Arc - Using the "Arc" you can make your audio signal change over time in intensity. Square - Using the "Square" you can make your audio signal vary in intensity with a sine wave.

Exponential - Using the "Exponential" you can make your audio signal vary in intensity over time. Logarithm - Using the "Logarithm" you can make your audio signal change over time in intensity. 2 Axioms: Using the "Axioms" you can use mathematical functions like Logarithm, Morph, Terrain, etc.

Can listen to Mode #

1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22,23,

24,25,26,27,28,29,30,31,32. Input # 1 and # 2. Each input channel has 4 position that can be set to high or low, left or right. Choosing the algorithm for each input channel. Use the "Select" knob to choose a mode from the list of 32. Use the "Play" button

LogiMod With Key

Q: What is KEYMACRO? A: KEYMACRO is a sound module that changes the pitch of a sound using the keyboard. With KEYMACRO, you can add effects like echo, reverb, vibrato, pitch shifting and much more. Q: How does the keyboard control the pitch? A: The keyboard controls the pitch by changing the depth of the oscillator. The higher the oscillator depth, the lower the pitch. So with the keyboard, you have a 12 o'clock position (12 o'clock = maximum depth) and then each note from 1 to 12. So for C, you would set the depth to C5, the 12 o'clock position. Q: Why should I use KEYMACRO? A: Using KEYMACRO is very easy. With a keyboard and a mouse, you can create a very wide range of sound effects. Q: How do I use KEYMACRO? A: KEYMACRO is very easy to use. To modify the pitch of a sound, simply press the key you want to change the sound. To stop the pitch changing, press the key again. Q: How do I get KEYMACRO? A: KEYMACRO is free for anyone to use. You can download the source code on www.keymacro.net. You can also buy the commercial version

for just \$25. Show HN: My weekend project, Write.io, is free and open source - amichail ===== JeffJenkins This looks really cool. I tried it out and it worked, but I had to click around a bit to figure out where to write things. It would be nice if there was an easy way to see the entirety of my data. I think I also had problems figuring out how to put multiple tags on a line. I put a " " in front of the tag, but it's not really clear to the user that that's the correct thing to do. I think that if you just made the first and last tag work together, instead of doing it like this you might be able to make it more clear to the user that they can put multiple tags per line. I think that you may be able to get more usage out of this if you could collapse the tags in the note to a unified, standardized (not HTML formatted) 2edc1e01e8

- One analog input channels - Algorithms are pre-defined and can be changed via the DIP switch or in the GUI - Easy to use (GUI) Reference input and output connectors: - In reference to the module, there are four main wires that will be used to feed and read information from the module. The Black Wire is Input A. The Red Wire is Input B. The White Wire is Output. The Green Wire is Ground. - The module will have a switch to activate the GUI and change the input and output connectors to the ones that you want to reference. - If you are using the module for a vehicle or DC motor, a power tap is also included. The module will give a true analog output from 0V to 5V. All the signals are not exactly same. This is the worst output voltage that the module will give. The modules are shipped empty with no components. All you have to do is connect the module to your circuits and power it. Features: - DIP Switch allows the user to change algorithms via a graphical user interface. - Clear on the screen when a channel is off. - 4 output connectors and a power tap for using the module on DC motors and other analog circuits. - Input wires can be referenced to any analog input. This is a very simple circuit, it is an alternative to the Microtroller. This is only a start and is not finished. To make this circuit better I need to add feedback. I used an LM741 Opamp for this. The LM741 will provide a smooth transition between any two voltages from 0V to 5V, in a short amount of time. It will not saturate at any given input voltage, which is required by the LogiMod.

There is a very small amount of output capacitance from the LM741. This is the simplest "Mooch" circuit that I've ever designed. It is based on the "LogiMod" by Raul Garcia. I'm going to use this as a starting point to build a "Mooch" that can be used to drive an array of motors, very inexpensive. I plan on designing a more powerful version that will also have a powertap and LED to indicate power. This is a TLC5913 driver IC with the Schottky diode across the anode pins, and a zener diode across the cathode pin.

What's New In?

Unstable channel is a mathematical algorithm that allows you to create an effect similar to an ELF oscillator. Impulse is a mathematical algorithm that will create a "vibrato" type effect. You can set the amount of frequency, depth and volume. X Over X is a mathematical algorithm that adds or multiplies two input signals together. The result can be pitched in different ways. Delay is a mathematical algorithm that adds or multiplies the input signal with an offset signal.

You can set the offset amount in milliseconds. Tap Delay is a mathematical algorithm that adds or multiplies the input signal with an offset signal. You can set the amount of frequency in Hz. Rotary is a mathematical algorithm that rotates two input signals by a certain amount. It can be used to create a "flange" effect. Auto Filt is a mathematical algorithm that will automatically filter the input signal. You can set the filter type, cutoff frequency and gain. Parametric is a mathematical algorithm that is used to modify the filter characteristics. You can set the type of filter, the amount of frequency, the amount of Q, gain and input gain. LO Filter is a mathematical algorithm that will apply an oscillator type effect to the filter output. You can set the oscillator type, frequency, amplitude, offset and phase. All of the algorithms can be used in groups, "modes" or individually. LogiMod Features: Signal input: x2 Input signal. Analog or digital. Input signal. Analog or digital. Channel: The "chaining" of the different algorithms. The "chaining" of the different algorithms. Slope: The amount of input signal to be multiplied or added. The amount of input signal to be multiplied or added. Depth: The amount of time that the input signal will stay in effect. The amount of time that the input signal will stay in effect. Fade: The amount of time between when the input signal fades away and when it fades in again. The amount of time between when the input signal fades away and when it fades in again. Volume: The amount of input signal that is multiplied or added to the output signal. The amount of input signal that is multiplied or added to the output signal. Pitch: The amount of output signal that is

added or multiplied by the input signal. The amount of output signal that is added or multiplied by the input signal. Gain: The amount of input signal that is added or multiplied to the output signal. The amount of input signal that is added or multiplied to the output signal. Output Gain: The amount of input signal that is added or multiplied to the output signal. The amount of input signal that is added or multiplied to the output signal. Delay: The amount of delay that the
